Selenols Catalyze the Interchange Reactions of Dithiols and Disulfides in Water

Rajeeva Singh and George M. Whitesides

Department of Chemistry, Harvard University, Cambridge, Massachusetts 02138

Received April 2, 1991

The mechanism of thiol–disulfide interchange reaction involves the nucleophilic attack of thiolate along the S–S bond axis of the disulfide.\(^1\) The reaction is kinetically second order: first order in thiolate and in disulfide.\(^2\) At pH 7, only 0.1–1% of typical thiol groups is present as thiolate in water, and the apparent rate constant of the thiol–disulfide interchange reaction is small (\(k_{\text{app}} = 0.1\) M\(^{-1}\) s\(^{-1}\)).\(^3\) Protein disulfide isomerase (EC 5.3.4.1) has been suggested to act as a catalyst for thiol-disulfide interchange in vivo, but its lack of specificity and the fact that it induces only moderate rate enhancements make its biological role uncertain.\(^4\)

As part of a program examining thiolate–disulfide interchange, we surveyed a number of types of compounds (aromatic thiols, nonthiol nucleophiles, and cations) as potential catalysts for this reaction. The only significant rate enhancement was obtained with phenylselenol.\(^5\) Selenolate is a strong nucleophile toward diselenides and a good leaving group in selenolate–diselenide interchange.\(^6\) The \(pK_a\) of selenols is \(7,11\) and at pH 7 the attack of selenol on diselenide is rapid (\(k_{\text{app}} = 1.65 \times 10^7\) M\(^{-1}\) s\(^{-1}\)).\(^7\) We expected selenolate to be a strong nucleophile toward disulfide and to be a good leaving group in the attack of thiolate on selenosulfide (RS–SeR). Scheme I shows the steps involved in the catalysis of a thiol–disulfide interchange reaction by selenol.

Reactions were carried out in buffered deoxygenated aqueous solution at room temperature (23-24 °C) under an atmosphere of argon. The error in the observed rate constants is ±10%. The initial concentrations of thiols and disulfides were 4 mM each in the UV experiments, 10 mM each in all other NMR experiments. The quantity of RSeH used is given in terms of equivalents of the reactants—thiols and disulfides. The equivalent of RSeH reported are two times the initial molar equivalents of (*H$_3$NCH$_2$CH$_2$Se)$_2$. The values of the uncatalyzed rate constant, $k_{\text{uncat}}$, for the HOCH$_2$CH$_2$SeCN experiments are assumed to be the same as determined by the NMR method for (*H$_3$NCH$_2$CH$_2$Se)$_2$ experiments.

Results and Discussion

Table I shows the apparent rate constants ($k_{\text{obsd}}$) of thiol–disulfide interchange reactions in the presence or absence of selenols. The reactions involving strongly reducing dithiols (eqs 1 and 2; DHA is dihydroasparagusic acid) are significantly catalyzed by the presence of alkyl selenols. Figure 1 illustrates the rate enhancements observed in these thiol–disulfide interchange reactions in the presence of catalytic amounts of selenol.

Table I reports observed rate enhancements ($k_{\text{obsd}}/k_{\text{uncat}} = v_{\text{cat}}/v_{\text{uncat}}$) and ratios of observed rate constants adjusted for the initial concentration of selenol ($k_{\text{obsd cat}}/[\text{RSeH}]_{\text{obsd cat}}$) estimated from eqs 3 and 4. We emphasize that these are

$$v_{\text{uncat}} = \frac{1}{2}d[\text{ME}] / dt = k_{\text{obsd uncat}}[\text{ME}]^2[R(\text{SH})_2]$$

$$v_{\text{cat}} = \frac{1}{2}d[\text{ME}] / dt = k_{\text{obsd cat}}[\text{ME}]^2[R(\text{SH})_2]$$

$K_{eq} = [\text{AESeH}]^2[\text{DTT}^\text{ox}] / [\text{AESeH}][\text{DTT}] = 0.14$ M

Strongly reducing dithiols (e.g., dithiothreitol (DTT)) reduce selenide to selenol. The value of the equilibrium constant (0.14 M, eqs 5 and 6) for the reduction of selenol.

$$K_{eq} = [\text{AESeH}]^2[\text{DTT}^\text{ox}] / [\text{AESeH}][\text{DTT}] = 0.14$$ M

Monothiols are more weakly reducing selenolate ((*H$_3$NCH$_2$CH$_2$Se)$_2$). AESeH by DTT is, however, significantly lower than that (9.4 x 10$^4$ M) for the analogous reduction of bis(2-hydroxyethyl) disulfide (ME$\text{ox}$) by DTT. 11

References

than with diithiols such as DTT and cannot reduce diselenide significantly (eq 7). The rate of thiol–disulfide interchange

\[ 2\text{ME} + \text{AESe}^{\text{ox}} \rightleftharpoons \text{ME}^\text{th} + 2\text{AESeH} \]

reaction of cysteine (or N-acetylcysteine) with bis(2-hydroxyethyl) disulfide (ME\textsuperscript{th}) is not enhanced in presence of 2-aminoethaneselenol (\( \text{H}_2\text{NCH}_2\text{CH}_2\text{SeH} \)) or 2-hydroxyethaneselenol (HOCH\textsubscript{2}CH\textsubscript{2}SeH) (Table I). The thiol–disulfide reactions involving monothiols and disulfides are not catalyzed by selenol because selenol is oxidized to diselenide by reaction with disulfide.

In the reactions involving strongly reducing diithiols and disulfides, the catalytic selenol can be generated from diselenide (RSeSeR) or selenocyanate (RSeCN). The addition of diselenide or selenocyanate to the reaction mixture is more convenient than the addition of selenols because selenols are easily oxidized and are thus difficult to manipulate.

In conclusion, selenols catalyze the thiol–disulfide interchange reactions involving diithiols significantly in water. They are the first nonbiological materials that have even marginal utility as catalysts for this reaction. We hypothesize, in the absence of any firm, relevant experimental evidence that this catalytic activity is attributable to their acidity (\( pK_a \approx 7 \), a number that probably provides a near-optimal combination of conversion of selenol to negatively charged selenolate nucleophile at pH 7 and useful nucleophilicity of this species) and to the weak solvation and high polarizability (and hence high nucleophilicity) of the selenolate ion. Thiolate–disulfide interchange reactions involving monothiols are, however, not accelerated in the presence of selenols. Selenols are oxidized to diselenides by noncyclic dialkyl disulfides. Their ability to catalyze reactions of eqs 1 and 2 is due to the ability of the diithiols to reduce diselenides to selenols.

The selenol precursors—diselenide or selenocyanate—can also be conveniently used to catalyze the thiol–disulfide interchange reactions involving strongly reducing diithiols.

**Experimental Section**

**General.** Selenocystamine hydrochloride (AESe\textsuperscript{ox}), potassium selenocyanate, 2-bromoethanol, dithiothreitol (DTT), cysteine (t-Cys), N-acetylcysteine (N-AcCys), and bis(2-hydroxyethyl) disulfide (ME\textsuperscript{th}) were all purchased from Aldrich. Dihydroaspargusic acid (DHA) was prepared as described. 2-Hydroxyethyl selenocyanate (HOCH\textsubscript{2}CH\textsubscript{2}SeCN) was prepared by a literature procedure. 17

All flasks, quartz cuvettes, and NMR tubes were stoppered with rubber septa and were flushed with argon before use. All solutions were deoxygenated by bubbling argon through them for ~45 min. All transfers were done using gas-tight syringes.

**Preparation of 2-Aminoethaneselenol (H\textsubscript{2}NCH\textsubscript{2}CH\textsubscript{2}SeH).** To a solution of selenocystamine hydrochloride (0.0028 g, 8.8 \( \mu \)mol) in deoxygenated ethanol (0.5 mL) was added sodium borohydride (0.0020 g, 53 \( \mu \)mol). The resulting solution was kept at room temperature under argon for 20 min until the solution became clear and no effervescence was seen. The solution was cooled in an ice bath and was quenched with glacial acetic acid (18 \( \mu \)L, 310 \( \mu \)mol). The concentration of 2-aminoethaneselenol was 40 mM by Ellman's assay. 20

**UV Assay for Catalysis of Thiol–Disulfide Interchange Involving DHA and ME\textsuperscript{th} by 2-Aminoethaneselenol (H\textsubscript{2}NCH\textsubscript{2}CH\textsubscript{2}SeH).** Stock solutions of DHA and ME\textsuperscript{th} (both 8 \( \mu \)M) were prepared from DHA (0.0131 g) in 10.5 mL of deoxygenated phosphate buffer (0.1 M in phosphate, pH 7.0, 2 mM in EDTA), and from ME\textsuperscript{th} (0.0129 g) in 10.5 mL of deoxygenated phosphate buffer. In a quartz cuvette containing 1.5 mL of DHA stock solution and 30 \( \mu \)L of 2-aminoethaneselenol stock solution (40 mM) was added 1.5 mL of ME\textsuperscript{th} stock solution, and the increase in absorbance at 310 nm was recorded. The initial concentrations in the cuvette were \([\text{DHA}] = [\text{ME}^{\text{th}}] = c_{\text{initial}} = 4.0 \text{mM}, \ [\text{H}_2\text{NCH}_2\text{CH}_2\text{SeH}] = 0.4 \text{mM} \). The apparent rate constant (\( k_{\text{obsd}} \)) was calculated using the integrated form of the rate equation (1) [DHA]/\( \text{dt} \) = \( k_{\text{obsd}} \) [DHA] [ME\textsuperscript{th}]: \( k_{\text{obsd}} = (1/c_{\text{initial}} - 1)/c_{\text{initial}}/t \). For monitoring the reactions of DTT and ME\textsuperscript{th}, the increase in absorbance at 310 nm was recorded. 21

**NMR Assay for Catalysis of Thiol–Disulfide Interchange Involving DTT and ME\textsuperscript{th} by 2-Aminoethaneselenol (H\textsubscript{2}NCH\textsubscript{2}CH\textsubscript{2}SeH).** Solutions of DTT (10 mM, 0.0031 g in 2 mL of deoxygenated \( \text{D}_2\text{O} \) buffer (50 mM in phosphate, pH 7.0)) and ME\textsuperscript{th} (10 mM, 0.0046 g in 3 mL of deoxygenated \( \text{D}_2\text{O} \) buffer) were prepared. To an NMR tube was added \( \text{H}_2\text{NCH}_2\text{CH}_2\text{SeH} \) (21 mL of a 11.8 mM solution in ethanol), and the solvent was removed in vacuo; to the NMR tube were added 0.25 mL of the DTT solution and 0.25 mL of the ME\textsuperscript{th} solution, and the reaction was quenched after 1.5 min by addition of DCI (10 \( \mu \)L of a 37 wt % solution in \( \text{D}_2\text{O} \)). The initial concentrations in the NMR tube were \([\text{DTT}] = [\text{ME}^{\text{th}}] = 5 \text{mM}, \ [\text{H}_2\text{NCH}_2\text{CH}_2\text{SeH}] = 0.5 \text{mM} \). The final concentrations of ME\textsuperscript{th} and ME were determined by integration of the NMR peak areas. For the uncatalyzed reaction, 0.25 mL of DTT solution and 0.25 mL of ME\textsuperscript{th} solution were mixed in an NMR tube, and the reaction was quenched after 5 min by addition of DCI (10 \( \mu \)L of a 37 wt % solution in \( \text{D}_2\text{O} \)).

(18) Selenols can be conveniently prepared by reduction of diselenide (RSeSeR) or selenocyanate (RSeCN) with sodium borohydride, or with diithiothreitol (DTT). Selenocyanates are conveniently prepared from alkyl bromide by reaction with potassium selenocyanate (KSeCN). 37

(19) We believe that reduction of the disulfide groups of cystines in proteins by diithiothreitol in water would be accelerated by catalytic amounts of selenols, but we have not tested this belief experimentally.
