Enzyme-Catalyzed Organic Synthesis: NAD(P)H Cofactor Regeneration Using Ethanol/Alcohol Dehydrogenase/Aldehyde Dehydrogenase and Methanol/Alcohol Dehydrogenase/Aldehyde Dehydrogenase/Formate Dehydrogenase

Summary: An enzyme-catalyzed system potentially applicable to large-scale synthesis is described.

Sir: We have recently described a number of methods for regeneration of NAD(P)H from NAD(P)+ for use in enzyme-catalyzed organic syntheses requiring nicotinamide cofactors. In this paper we compare two additional useful schemes, and apply these schemes to syntheses producing 0.1-0.5-mol quantities of products (Figure 1). The first method is based on catalysis by two enzymes—alcohol dehydrogenase (ADH, EC 1.1.1.1) and aldehyde dehydrogenase (AldDH, EC 1.2.1.5)—and converts ethanol to acetate. This scheme has been demonstrated previously in millimole-scale syntheses. The second uses ADH, AldDH, and formate dehydrogenase (FDH, EC 1.2.1.2) and converts methanol to CO2. The first generates 2 equiv of reduced nicotinamide cofactor/equiv of ethanol, and accepts either NAD+ or NADP+; the second generates 3 equiv of reduced nicotinamide cofactors/equiv of methanol but accepts only NAD+. The relevant kinetic parameters for the enzymes in these schemes are summarized in Table I. The only feature of these parameters which requires specific comment concerns ADH: the enzyme from Saccharomyces cerevisiae has high specific activity with ethanol but is specific for NAD+; that from Leuconostoc mesenteroides reduces both NAD+ and NADP+ but has lower specific activity.

In a representative procedure for NADH regeneration using ethanol as ultimate reducing agent (A, Figure 1), a 500-mL solution containing potassium pyruvate (15.1 g, 120 mmol), NAD+ (50 pmol), ethanol (3.3 g, 70 mmol), and p-mercaptoethanol (39 mg, 0.5 mmol) was mixed with PAN-immobilized yeast ADH (90 units, 0.5 mL of gel), AldDH (110 units, 10 mL of gel), and L-lactic dehydrogenase (L-LDH, 200 units, 0.5 mL of gel). The reaction mixture was stirred at 25 °C under argon, and the pH of the solution was controlled automatically at 8.0-8.2 by adding 2 N KOH through a peristaltic pump. More ethanol (3.3 g, 60 mmol) was added after 1 day. The reaction was complete in 2 days. The solution, after removal of the enzyme-containing gel, was concentrated to 20 mL and acidified with concentrated H2SO4 to pH 2.8, followed by addition of ethanol (200 mL). The precipitates were separated by filtration and discarded, and the filtrate was concentrated at room temperature to an oily residue. The residue was diluted with water (150 mL) and neu-

Figure 1. A: Regeneration of NAD(P)H using ethanol and alcohol dehydrogenase/alddehyde dehydrogenases. B: Regeneration of NADH using methanol and alcohol dehydrogenase/alddehyde dehydrogenase/formate dehydrogenase. Abbreviations: ADH, alcohol dehydrogenase from yeast (for NAD) or from L. mesenteroides (for NAD or NADP); AldDH, aldehyde dehydrogenase; GluDH, glutamic dehydrogenase; FDH, formate dehydrogenase.

AldDH was immobilized with PAN 1000 in the presence of acetaldehyde (5 mM) and NAD+ (2 mM), in 50% yield. FDH was immobilized in the presence of formate (20 mM) and NAD+ (2 mM), in 40% yield.
factor and methanol as ultimate reducing agent is illus-
rated by adding ZnCO₃ (8.2 g, 65 mmol) to obtain crystalline zinc L-lactate (32.6 g of solid containing 96% zinc bis(L-lactate) trihydrate (106 mmol); 88% yield and 94% ee). The turnover number (TN) and residual activities were as follows: ADH, 70%; AldDH, 70%; L-LDH, 78%. The advantages and disadvantages of these systems are listed in Table II. The balance of these characteristics remains as low as possible and protects the enzymes from deactivation.

In a typical procedure illustrating the operation of ADH/AldDH for NADPH regeneration, a 500-mL solution containing potassium pyruvate (22 g, 120 mmol), NADP⁺ (50 μmol), and ethanol (3.3 g, 70 mmol) was neutralized by adding NH₄OH to pH 8.0-8.2. β-Mercaptoethanol and PAN-immobilized ADH from L. mesenteroides (90 units based on NADP⁺, 1 mL of gel), AldDH (92 units based on NADP⁺, 25 mL of gel) and glutamic dehydrogenase (GluDH, 100 units, 1 mL of gel) were added. The reaction was conducted at pH 8.2 and was complete in 2 days. The decanted solution was concentrated to ~100 mL, adjusted to pH 6.5, and treated with ethanol (80 mL) until the solution became turbid. A crystalline solid (20 g) containing 97% of monopotassium L-glutamate (104 mmol, 86% yield) was obtained after cooling. The TN and residual activities were as follows: NADP⁺, 2400 (82%); GluDH, 1 x 10⁶ (88%); ADH, 2 x 10⁵ (86%); AldDH, 1 x 10⁶ (86%).

The operation of the redox system using NAD⁺ as co-factor and methanol as ultimate reducing agent is illustrated by a preparation of L-lactate. A 600-mL solution containing potassium pyruvate (15 g, 120 mmol), NAD⁺ (10 μmol), yeast ADH (30 units, 15 mL of gel, activity based on methanol as substrate), AldDH (34 units, 6 mL of gel, activity based on formaldehyde as substrate), FDH (30 units, 12 mL of gel), and L-LDH (50 units, 0.5 mL of gel) was deoxygenated with Ar, followed by addition of methanol (1.5% v:v, 0.3 M) and mercaptetoethanol (final concentration, 4 mM). The pH of the reaction mixture was controlled at 8.0-8.2. After 4 days, l-lactate was isolated as its zinc salt (16.2 g, 94% purity, 86% yield, 92% ee). The TN and residual activities were as follows: NAD⁺, 1200 (90%); FDH, 3.2 x 10⁶ (88%); ADH, 3 x 10⁵ (82%); AldDH, 9 x 10⁵ (86%); L-LDH, 1.8 x 10⁵ (96%).

The most important feature of these preparations is the use of ratios of AldDH/ADH/FDH such that the first step (formation of aldehyde) is the slow step. This protocol insures that the aldehyde concentration in the reactor remains as low as possible and protects the enzymes from deactivation.

The advantages and disadvantages of these systems are listed in Table II. The balance of these characteristics is that these systems are potentially more economical for nicotinamide cofactor regeneration in connection with large-scale synthesis than most others but are somewhat less convenient for laboratory-scale (~0.1–10 mol) syntheses than those based on glucose 6-phosphate or formate. We note that it should be relatively straightforward by recombinant DNA techniques to produce microorganisms having high contents of the two or three enzymes required in these schemes in the correct ratios.
for optimum performance. The use of immobilized whole organisms of this type, or of crude extracts from them, would be the most efficient method for preparation of the required enzymatic activities.

**Registry No.** NADH, 58-68-4; NAD⁺, 53-84-9; NADPH, 53-57-6; NADP⁺, 53-59-8; ADH, 9031-72-5; AldDH, 9028-88-0; FDH, 9028-85-7; ethanol, 64-17-5; methanol, 67-56-1.
